Association of Plasma Neurofilament Light With Neurodegeneration in Patients With Alzheimer Disease

Niklas Mattsson, MD, PhD; Ulf Andreasson, PhD; Henrik Zetterberg, MD, PhD; Kaj Blennow, MD, PhD; for the Alzheimer’s Disease Neuroimaging Initiative

**IMPORTANCE** Existing cerebrospinal fluid (CSF) or imaging (tau positron emission tomography) biomarkers for Alzheimer disease (AD) are invasive or expensive. Biomarkers based on standard blood test results would be useful in research, drug development, and clinical practice. Plasma neurofilament light (NFL) has recently been proposed as a blood-based biomarker for neurodegeneration in dementias.

**OBJECTIVE** To test whether plasma NFL concentrations are increased in AD and associated with cognitive decline, other AD biomarkers, and imaging evidence of neurodegeneration.

**DESIGN, SETTING, AND PARTICIPANTS** In this prospective case-control study, an ultrasensitive assay was used to measure plasma NFL concentration in 193 cognitively healthy controls, 197 patients with mild cognitive impairment (MCI), and 180 patients with AD dementia from the Alzheimer’s Disease Neuroimaging Initiative. The study dates were September 7, 2005, to February 13, 2012. The plasma NFL analysis was performed in September 2016.

**MAIN OUTCOMES AND MEASURES** Associations were tested between plasma NFL and diagnosis, Aβ pathologic features, CSF biomarkers of neuronal injury, cognition, brain structure, and metabolism.

**RESULTS** Among 193 cognitively healthy controls, 197 patients with mild cognitive impairment, and 180 patients with AD dementia, plasma NFL correlated with CSF NFL (Spearman ρ = 0.59, P < .001). Plasma NFL was increased in patients with MCI (mean, 42.8 ng/L) and patients with AD dementia (mean, 51.0 ng/L) compared with controls (mean, 34.7 ng/L) (P < .001) and had high diagnostic accuracy for patients with AD dementia vs controls (area under the receiver operating characteristic curve, 0.87, which is comparable to established CSF biomarkers). Plasma NFL was particularly high in patients with MCI and patients with AD dementia with Aβ pathologic features. High plasma NFL correlated with poor cognition and AD-related atrophy (at baseline and longitudinally) and with brain hypometabolism (longitudinally).

**CONCLUSIONS AND RELEVANCE** Plasma NFL is associated with AD diagnosis and with cognitive, biochemical, and imaging hallmarks of the disease. This finding implies a potential usefulness for plasma NFL as a noninvasive biomarker in AD.
Alzheimer disease (AD) is a neurodegenerative disease that is characterized by brain accumulation of β-amyloid (Aβ) and tau, progressive atrophy, and cognitive decline. Biomarkers that capture biological processes in AD are increasingly used to support the diagnosis of AD in research, drug development, and clinical practice. The most well-established AD biomarkers include structural magnetic resonance imaging (MRI); cerebrospinal fluid (CSF) biomarkers of Aβ, tau, and neuronal injury; and positron emission tomographic imaging of Aβ, tau, and brain metabolism. Use of these biomarkers is hampered by a high degree of invasiveness, high costs, or limited availability. Blood-based biomarkers for AD may allow for efficient monitoring of disease processes in AD and could be used as a screening tool in primary care. One potential blood-based biomarker for AD is the neuronal injury marker neurofilament light (NFL) because patients with AD have increased CSF concentrations of NFL. Results from some studies suggest that patients with AD have increased plasma NFL concentrations. However, those studies were performed using standard immunoassay techniques with suboptimal analytical sensitivity to accurately quantify low abundant brain-specific proteins in blood samples. For this reason, our group has recently transferred the CSF NFL assay to an ultrasensitive single-molecule array platform using a home brew kit (NF-light; UmanDiagnostics), transferred onto the ultrasensitive single-molecule array and correlate closely with the corresponding CSF concentrations. Herein, we test this novel plasma NFL assay in patients with AD for the first time, to our knowledge. We studied cognitively healthy control individuals, patients with mild cognitive impairment (MCI) (MCI group), and patients with AD dementia (AD group) in a large prospective study. We tested the hypotheses that the plasma NFL concentration is increased in AD and that it correlates with impaired cognition, neuroimaging abnormalities, and CSF biomarkers of AD pathologic features.

Methods

ADNI Study Design

Data were obtained from the Alzheimer’s Disease Neuroimaging Initiative (ADNI) database (http://adni.loni.usc.edu). The ADNI was launched in 2003 as a public-private partnership, led by principal investigator Michael W. Weiner, MD (the most recent information on the ADNI is available at http://www.adni-info.org). The ADNI participants have been recruited from more than 50 sites across the United States and Canada. For the present study, we used data accessed from the Laboratory of Neuro Imaging (University of Southern California) ADNI database on October 6, 2016. The study data and samples were collected from September 7, 2005, to February 13, 2012. Regional ethical committees of all participating institutions approved the ADNI. All study participants provided written informed consent.

Findings

In this case-control study of 193 cognitively healthy controls, 197 patients with mild cognitive impairment, and 180 patients with Alzheimer disease dementia, plasma neurofilament light was associated with Alzheimer disease and correlated with future progression of cognitive decline, brain atrophy, and brain hypometabolism.

Key Points

**Question** What is the importance of plasma neurofilament light in Alzheimer disease?

**Findings** In this case-control study of 193 cognitively healthy controls, 197 patients with mild cognitive impairment, and 180 patients with Alzheimer disease dementia, plasma neurofilament light was associated with Alzheimer disease and correlated with future progression of cognitive decline, brain atrophy, and brain hypometabolism.

**Meaning** Plasma neurofilament light may be a promising noninvasive biomarker for Alzheimer disease.

ADNI Participants

Our ADNI cohort consisted of all cognitively healthy controls, patients with MCI, and patients with AD dementia with available baseline plasma NFL samples from the ADNI-1. Inclusion and exclusion criteria were described in detail previously. Briefly, all ADNI-1 participants were aged 55 to 90 years, had completed at least 6 years of education, were fluent in Spanish or English, and had no substantial neurological disease other than AD. Controls had Mini-Mental State Examination (MMSE) scores of 24 or higher, where lower scores indicate more impairment and higher scores less impairment (range, 0-30), and a Clinical Dementia Rating (CDR) score of 0, where lower scores indicate less impairment and higher scores more impairment (range, 0-3). Patients with MCI had MMSE scores of 24 or higher, objective memory loss tested by delayed recall of the Wechsler Memory Scale (WMS) logical memory II (>1 SD below the normal mean), a CDR score of 0.5, preserved activities of daily living, and absence of dementia. Patients with AD dementia fulfilled the National Institute of Neurological Communicative Disorders and Stroke-Alzheimer Disease and Related Disorders Association criteria for probable AD, had MMSE scores of 20 to 26, and had CDR scores of 0.5 to 1.0.

Plasma NFL

Plasma NFL concentrations were measured using an NFL kit (NF-light; UmanDiagnostics), transferred onto the ultrasensitive single-molecule array platform using a home brew kit (Simoa Homebrew Assay Development Kit; Quanterix Corporation), as previously described. In the 14 analytical runs needed to complete the study, the relative error of the back-calculated concentrations was below 20% for all calibrators, run in triplicate, resulting in lower limits of quantifications of 2.2 ng/L and upper limits of quantification of 1620 ng/L. All samples measured within the range spanned by the limits of quantifications, and for the low-concentration quality control sample (14 ng/L), the intra-assay coefficient of variation was 11.0% and the interassay coefficient of variation was 11.1%. For the high-concentration quality control sample (137 ng/L), the corresponding coefficients of variation were 8.8% and 9.6%, respectively. The measurements were performed in September 2016 by a board-certified laboratory technician using a single batch of reagents.
Plasma Neurofilament Light and Neurodegeneration in Alzheimer Disease

**Abbreviations:** Aβ, β-amyloid; AD, Alzheimer disease dementia; CSF, cerebrospinal fluid; MCI, mild cognitive impairment; MMSE, Mini-Mental State Examination; NFL, neurofilament light; p-tau, phosphorylated tau; t-tau, total tau.

*P* values are from the Kruskal-Wallis test or Fisher exact test. β-Amyloid positivity was defined as CSF Aβ42 less than 192 ng/L.

### CSF Measurements

Cerebrospinal fluid was sampled by lumbar puncture from a subset of the participants, with CSF Aβ42, CSF total tau (t-tau), and CSF phosphorylated tau (p-tau) measured using a multiplex platform (xMAP; Luminex Corporation) with a kit (INNO-BIA AlzBio3; Fujirebio Europe). Participants were classified as Aβ positive or Aβ negative using a previously established cutoff (CSF Aβ42 < 192 ng/L). We excluded 8 patients with AD dementia who were Aβ negative and therefore likely to be misdiagnosed. The CSF NFL concentrations were measured using a commercial ELISA (NF-light; UmanDiagnostics) and have been reported previously. In total, we included CSF data from 112 controls, 189 patients with MCI, and 90 patients with AD dementia.

### Cognition

Cognition was assessed by MMSE, Alzheimer Disease Assessment Scale–cognitive subscale (ADAS-Cog II), delayed recall of the WMS logical memory II, Trail-Making test part B (TMT-B), and Wechsler Adult Intelligence Scale–Revised (WAIS-R) digit symbol substitution test. All tests were administered at baseline and at 6, 12, 18, 24, 36, and 48 months, except for delayed recall of the WMS logical memory II, which was not assessed at 18 months.

### Neuroimaging

Structural brain images were acquired using 1.5-T MRI imaging systems with T1-weighted MRI scans using a sagittal volumetric magnetization-prepared rapid acquisition gradient echo sequence (at baseline and at 6, 12, 18, 24, 36, and 48 months). A software program (FreeSurfer; https://surfer.nmr.mgh.harvard.edu/) was used for quantification of cortical thickness and subcortical volumes. We used volumetric data for hippocampal volume and lateral ventricles (averaged between right and left sides). We used the mean cortical thickness for a set of regions defined a priori based on work by Jack et al to represent AD cortex (including entorhinal, inferior temporal, middle temporal, and fusiform cortex).

White matter hyperintensities (WMHs) were quantified at baseline and at 6, 12, 18, 24, 36, and 48 months using a fully automated protocol. Positron emission tomography with 18F-fluorodeoxyglucose image data were acquired at baseline and at 6, 12, 18, 24, 36, and 48 months. We created mean counts of the lateral and medial frontal, anterior, and posterior cingulate regions, as well as lateral parietal and lateral temporal regions.

### Statistical Analysis

We tested associations between plasma NFL and demographic factors using the Kruskal-Wallis test and Spearman rank correlation. We tested associations between biochemical markers and between plasma NFL and diagnosis using linear regression models. We calculated diagnostic accuracies using area under the receiver operating characteristic curve (AUROC) analysis with 10-fold cross-validated logistic regression models. We tested associations between plasma NFL concentrations and longitudinal cognition, brain structure, and brain metabolism using linear mixed-effects models. These models had random intercepts and slopes for time and an unstructured covariance matrix for the random effects and included the interaction between (continuous) time and plasma NFL as predictor. All outcome variables in linear mixed-effects models were standardized to z scores to facilitate comparisons between modalities. Therefore, β coefficients refer to standardized effects (β = 1 implies that an increase of 1 ng/L in plasma NFL was associated with a 1-SD increase in the dependent variable).

All tests were 2-sided. Statistical significance was set at *P* < .05. All regression analyses were corrected for age, sex, educational level, diagnosis, and APOE ε4 genotype, as well as intracranial volume for hippocampus and ventricles. All statistical analyses were performed using a software program (R, version 3.2.3; The R Foundation).

### Results

Table 1 lists demographics for the study population. In the whole cohort, plasma NFL correlated with age (Spearman *r* = −0.03, *P* = .58) but not with sex (median, 36.2 ng/L for men vs 37.4 ng/L for women; *P* = .98), educational level (*r* = −0.03, *P* = .52), or APOE ε4 genotype (37.7 ng/L in carriers vs 35.6 ng/L in noncarriers, *P* = .19). These results were similar within diagnostic groups, except that plasma NFL concentrations were higher in APOE ε4 carriers in the MCI group (35.9 ng/L in carriers vs 39.3 ng/L in noncarriers, *P* = .52, or Fisher exact test). β-Amyloid positivity was defined as CSF Aβ42 less than 192 ng/L.
Plasma NFL and Other Biochemical Markers in CSF and Plasma

Plasma NFL correlated with high CSF NFL (Spearman $\rho = 0.59$, $P < .001$) (Figure 1) and with low CSF Aβ42, high CSF t-tau, high CSF p-tau, and high plasma tau (Table 2). The strongest correlations were seen with CSF NFL, which were also present in all diagnostic groups. Plasma NFL also correlated with CSF Aβ42 and CSF t-tau in the MCI group, as well as with plasma tau concentrations in all diagnostic groups.

Plasma NFL in Different Diagnostic Groups

Plasma NFL concentrations were higher in the AD group compared with controls and the MCI group, as well as in the MCI group compared with controls (Figure 2A). Plasma NFL differentiated between the AD dementia group and controls, with an AUROC of 0.87 (Figure 2B). By comparison, the AUROCs were 0.87 to 0.90 for CSF NFL, CSF t-tau, and CSF p-tau and 0.78 for plasma tau. These AUROCs were corrected for age, sex, educational level, and $APOE$ ε4 genotype.

Abbreviations: AD, Alzheimer disease; CSF, cerebrospinal fluid; MCI, mild cognitive impairment; NFL, neurofilament light; p-tau, phosphorylated tau; t-tau, total tau.

Data are $\beta$ coefficients (with $P$ values) from linear regression models for correlations between plasma NFL and other biomarkers (all standardized to z scores), adjusted for age, sex, educational level, $APOE$ ε4 genotype, and diagnosis. Models were tested in the whole cohort and in individual diagnostic groups.
cortex ($\beta = -0.162$, $P < .001$ baseline and $\beta = -0.049$, $P < .001$ longitudinally) for the imaging measures (details are provided in the eTable in the Supplement).

We also tested whether the influence of plasma NFL differed between diagnostic groups. Statistically significant interactions were found at baseline for the MCI group and MMSE score ($\beta = -0.107$, $P = .008$), ADAS-COG 11 score ($\beta = 0.150$, $P = .002$), and delayed recall of the WMS logical memory II ($\beta = -0.167$, $P < .001$), TMT-B score ($\beta = 0.283$, $P < .001$), WAIS-R digit symbol substitution test score ($\beta = -0.253$, $P = .002$), and AD cortex ($\beta = -0.282$, $P < .001$), as well as for the AD group and MMSE score ($\beta = -0.133$, $P = .002$), ADAS-COG 11 score ($\beta = 0.171$, $P = .001$), delayed recall of the WMS logical memory II ($\beta = -0.117$, $P = .01$), and AD cortex ($\beta = -0.178$, $P = .04$). These results indicate that plasma NFL was more strongly correlated with the outcomes in the MCI group and the AD dementia group than in controls at baseline. Longitudinally, the only statistically significant interaction was for the MCI group and MMSE score ($\beta = -0.107$, $P = .003$), demonstrating that plasma NFL...
levels were more strongly correlated with longitudinal MMSE scores in the MCI group than in controls.

Discussion

We present the first large study, to our knowledge, on plasma NFL in AD dementia. The main findings were that plasma NFL (1) correlated with CSF NFL independent of diagnosis, (2) was increased in the AD dementia group and in Aβ-positive patients with MCI, (3) had diagnostic accuracy for AD dementia in the same range as established CSF biomarkers, and (4) was associated with cognitive deficits and neuroimaging hallmarks of AD at baseline and during follow-up. Together, these findings support that plasma NFL is a promising biomarker for neuronal injury in AD, which may have potential for prognosis and monitoring of disease progression. This biomarker may be useful in clinical studies, in drug development, and ultimately in clinical practice. However, increased plasma NFL concentrations are also found in several other neurodegenerative disorders, such as progressive supranuclear palsy, frontotemporal dementia, and human immunodeficiency virus with brain engagement, meaning that it lacks disease specificity for AD. Therefore, we do not envision plasma NFL as a tool to differentiate AD from other neurodegenerative diseases. Rather, it may be valuable as a general biomarker for neurodegeneration.

Plasma NFL correlated with CSF NFL levels in the whole cohort and in diagnostic groups. Although these correlations were statistically significant, particularly in the whole cohort, the correlation coefficients were slightly lower than what was seen in previous studies of plasma or serum NFL levels, which included individuals with human immunodeficiency virus,13 progressive supranuclear palsy,14 other neurological diseases,10 and minor neurosurgical trauma.21 Hypothetically, it is possible that a greater variability in plasma NFL concentrations in AD compared with previously tested diseases could have influenced the correlations between plasma NFL and CSF NFL. Plasma NFL also correlated with other CSF biomarkers in the whole cohort, but those correlations were often not statistically significant within diagnostic groups, suggesting that they were confounded by diagnosis. This finding probably reflects that several different pathologic conditions are present in AD (e.g., Aβ pathologic features, tau pathologic findings, and degeneration of different types of axons) and drive different biomarker responses, which will be weakly correlated overall. In MCI, a heterogeneous condition, high plasma NFL levels correlated with low CSF Aβ42 and high CSF t-tau,
and this correlation supports the use of plasma NFL as a biomarker sensitive to AD-related biological changes in prodromal AD. Plasma NFL also correlated with plasma tau in all diagnostic subgroups. Although plasma tau appears to be a weaker biomarker for neuronal injury than plasma NFL, these measures may partly reflect the same process (e.g., axonal degeneration).

The AD dementia group had higher plasma NFL levels than the MCI group, and the MCI group and the AD dementia group had higher plasma NFL levels than the controls. Although plasma NFL overlaps between the diagnostic groups, the accuracy of plasma NFL for AD dementia vs controls is close to established CSF AD biomarkers and much higher than for plasma tau (AUROC, 0.87 vs 0.78 when adjusted for demographics and APOE ε4; AUROC, 0.79 vs 0.64 when adjusted only for demographics). To our knowledge, this study represents the first time that a peripheral, noninvasive biomarker for neuronal injury has shown diagnostic accuracy for AD dementia comparable with established biomarkers in a large-scale multicenter cohort.

In the MCI group, plasma NFL levels were increased primarily in Aβ-positive patients with MCI (i.e., prodromal AD). Plasma NFL concentration did not differ between clinically stable and progressive Aβ-positive patients with MCI. This result may have been influenced by the short follow-up time used to define stable MCI (2 years), which may be too abbreviated to verify the benign nature of the so-called stable condition. The finding that plasma NFL concentrations were increased already in prodromal AD is promising because it may render plasma NFL more useful in drug development, which is largely focused on this early stage of AD, as well as in clinical practice because patients with MCI increasingly seek medical evaluation. Plasma NFL did not differ between Aβ-positive and Aβ-negative controls, suggesting that any neuronal injury that may occur in Aβ-positive controls (i.e., preclinical AD) is below the detection limit for plasma NFL. This result is well in line with the theory that preclinical AD is devoid of substantial neuronal injury.

The final major finding was that plasma NFL was associated with several cognitive and imaging AD hallmarks at baseline and when those measures were analyzed over time. Specifically, plasma NFL was associated with general cognition (MMSE score and ADAS-Cog 11 score) and executive function (TMT-B score) at baseline and with decline in all tested cognitive measures over time. The somewhat stronger correlations with timed tests, including TMT-B and WAIS-R digit symbol substitution test, compared with the memory test may suggest that plasma NFL primarily reflects damage to larger myelinated axonal processes of neurons. For imaging measures, associations were seen with lateral ventricles, hippocampal volume, and AD cortex thickness at baseline and over time, as well as with hypometabolism over time. The correlations were strongest in the MCI group and the AD dementia group but were statistically significant in the whole cohort when adjusting for diagnosis.

Limitations
This study is limited by the lack of patients with neurodegenerative diseases other than AD, which prevented our testing for disease specificity of plasma NFL. Another limitation is the restricted sample in the ADNI, such that patients with substantial vascular burden were excluded. This exclusion may have made it difficult to detect subtle associations between plasma NFL and white matter pathologic findings and may explain the surprising finding that plasma NFL did not correlate with WMHs, despite that CSF NFL has been considered a marker of white matter pathologic features, including in AD. Future studies should test plasma NFL in a more unselected group of patients with AD and may also explore different proxies for white matter injury. A larger age span should also be included in future work because it is possible that vascular comorbidities may change with age and alter the diagnostic accuracy of plasma NFL for patients with AD vs controls and other diseases.

All main results were in the expected directions, without illogical data. The main findings that plasma NFL concentration was increased in the AD dementia group and correlated with CSF NFL, imaging, and cognitive hallmarks of AD were all statistically significant. We believe that the consistency of these data makes it unlikely that they were falsely positive. Therefore, we reported P values uncorrected for multiple comparisons.

Conclusions
We found that plasma NFL concentration is increased in AD, even in prodromal disease, and that it correlates with important disease hallmarks, measured by cognitive tests, neuroimaging, and CSF biomarkers. The fact that plasma NFL concentration is also elevated in other neurological diseases and that NFL may be released from neurons in Aβ-dependent and Aβ-independent pathologic conditions argues against the use of plasma NFL for differential diagnosis of AD vs other dementias. However, plasma NFL may be a valuable noninvasive tool to assess neurodegeneration and to identify individuals at risk for future cognitive decline and brain atrophy. Therefore, plasma NFL is a promising peripheral biomarker for neurodegeneration, including in AD. In a clinical trial scenario, it is possible that plasma NFL may be used (together with demographics and APOE ε4 genotype data) to predict longitudinal disease progression. Future studies with repeated samples should test plasma NFL as a longitudinal noninvasive proxy for neurodegeneration.

Clinical Core Leaders: Mayo Clinic, Rochester, MN: Ronald Petersen, MD, PhD (Core PI); University of Southern California: Paul Aisen, MD.

Clinical Informatics and Operations: University of California San Diego: Robert J. Pantalone, PhD; Michael Donohue, PhD; Sarah Walter, MSc; Devon Gessert; Tamie Sather, MA; Gus Jiminez, MBS; Archana B. Balasubramanian, PhD, Jennifer Mason, MPH; Iris Sim.

Biostatistics Core Leaders and Key Personnel: University of California Davis: Laurel Beckett, PhD (Core PI); Danielle Harvey, PhD; University of California San Diego: Michael Donohue, PhD.

MRI Core Leaders and Key Personnel: Mayo Clinic, Rochester, MN: Clifford R. Jack Jr (Core PI); Matthew Bernstein, PhD; Brett Borowski, RT; Jeff Gunter, PhD; Matt Senjem, MS; Prashanthi Venmi, PhD; David Jones, MD, Kejal Kantarci; Chad Ward; University of London: Nick Fox, MD; UCLA School of Medicine: Paul Thompson, PhD; University of California San Francisco: Norbert Schuff, PhD; University of California Davis: Charles DeCarli, MD.

PET Core Leaders and Key Personnel: UC Berkeley: William Jagust, MD (Core PI); Susan Landau, PhD; University of Michigan: Robert A. Koeppe, PhD; University of Utah: Norm Foster, MD; Banner Alzheimer Institute: Eric M. Reiman, MD; Kewei Chen, PhD; University of Pittsburgh: Chet Mathis, MD.

Neuropathology Core Leaders: Washington University St. Louis: John C. Morris, MD; Nigel J. Cairns, PhD, FRCPath; Erin Franklin, MS, CCRP; Lisa Taylor-Reinwald, BA, HTL (ASCP) - Past Investigator.

Biomarkers Core Leaders and Key Personnel: University of Pennsylvania School of Medicine: Leslie M. Shaw, MD, PhD; John Q. Trojanowski, MD, PhD; Virginia Lee, PhD, MBA; Magdalena Korecka, PhD; Michal Figurski, PhD.

Informatics Core Leaders and Key Personnel: University of Southern California: Arthur W. Toga, PhD (Core PI); Karen Crawford; Scott Neu, PhD.

Genetics Core Leaders and Key Personnel: Indiana University: Andrew J. Saykin, PsyD; Tatiana M. Foroud, PhD; Li Shen, PhD; Kelley Faber, MS, CCRP; Sungae Kim, PhD; Kwangski Nho, PhD; University of California Irvine: Steven Potkin, PhD.

Initial Concept Planning & Development: University of California San Francisco: Michael W. Weiner, MD; University of California San Diego. Lean Thal, MD; Prevent Alzheimer’s Disease 2020: Zaven Khachaturian, PhD (Chair).

Early Project Proposal Development: University of California San Diego: Leon Thal, MD; Neil Buckholz National Institute on Aging; University of California San Francisco: Michael W. Weiner, MD; Brown University: Peter J. Snyder, PhD; National Institute of Mental Health: William Potter, MD; Cornell University: Steven Paul, MD; Johns Hopkins University: Marilyn Albert, PhD; Richard Frank Consulting; Richard Frank, MD, PhD; Prevent Alzheimer’s Disease 2020: Zaven Khachaturian, PhD (Chair).

NIA: National Institute on Aging: John Hsiao, MD, Investigators by Site: Oregon Health & Science University: Jeffrey Kaye, MD, Joseph Quinn, MD, Lisa Silbert, MD; Betty Lind, BS; Raina Carter, BA – Past Investigator; Sara Dolen, BS – Past Investigator. University of Southern California: Lon S. Schneider, MD; Sonia Pawluczyk, MD; Mauricio Becerra, BS; Liberty Teodoro, RN; Bryan M. Spann, DO – Past Investigator. University of California San Diego: James Brewer, MD, PhD; Helen Vanderswaag, RN; Adam Fleisher, MD – Past Investigator. University of Michigan: Judith L. Heidebrink, MD, MS; Joanne L. Lord, LPN, BA, CCRC – Past Investigator. Mayo Clinic, Rochester, MN: Ronald Petersen, MD, PhD; Sara S. Mason, RN; Colleen S. Albers, RN; David
Plasma Neurofilament Light and Neurodegeneration in Alzheimer Disease

Knoiman, MD, Kris Johnson, RN – Past Investigator.
Baylor College of Medicine: Rachelle S. Doody, MD, PhD, Javier Villanueva-Meyer, MD, Valery Pavlik, PhD; Victoria Shibley, MS; Munir Chowdhury, MBBS, MS – Past Investigator; Susan Rountree, MD – Past Investigator; Mimi Dang, MD – Past Investigator.
Columbia University Medical Center: Yaakov Stern, PhD; Lawrence S. Honig, MD, PhD; Karen L. Bell, MD; Washington University, St. Louis: Beau Ances, MD, PhD; Maria Carroll, RN, MSN; Mary L. Creese, RN, MSW; Erin Franklin, MS, MCCRP; Mark A. Mintun, MD – Past Investigator; Stacy Schneider, APRN, BC, GNP – Past Investigator; Angela Oliver, RN, BSN, MSN – Past Investigator. University of Alabama Birmingham: Daniel Marson, JD, PhD; David Gelernter, MD; Marissa Natalieon Love, MD; Randall Griffith, PhD, ABPP – Past Investigator; David Clark, MD – Past Investigator; John Brockington, MD – Past Investigator; Mount Sinai School of Medicine: Hillel Grossman, MD; Eilie Mitsis, PhD; Gaia Unzicker, MD – Past: Raj C. Shah, MD; Leyla de Toledo-Morrell, MD – Past Investigator; Wien Center: Ranjan Duara, MD; Maria T. Greig-Custo, MD; Warren Barler, MA, MS; Johns Hopkins University: Marilyn Albert, PhD; Chiaid Onyike, MD; Daniel D’Agostino II, BS; Stephanie Kiehl, PhD – Past Investigator; New York University: Martin Sadowski, MD; Mohammed O. Shehik, MD; Anaztasia Ulysse; Murinali Gaikwad. Duke University Medical Center: P. Murial Doraiswamy, MBBS, FRCP; Jeffrey R. Petrella, MD; Salvador Borges-Neto, MD; Terence Z. Wong, MD – Past Investigator; Edward Coleman – Past Investigator; University of Pennsylvania: Steven E. Arnold, MD; Jason H. Karlawish, MD; David A. Woll, MD; Christopher M. Clark, MD – Past Investigator; University of Kentucky: Charles D. Smith, MD; Greg Jicha, MD; Peter Hardy, PhD; Partha Sinha, PhD; Elizabeth Davies, MD; Gary Conrad, MD – Past Investigator; University of Pittsburgh: Oscar L. Lopez, MD; Mary Ann Oakley, MA; Donna M. Simpson, CRNP, MPH. University of Rochester Medical Center: Anton P. Porsteinsson, MD; Bonnie S. Goldstein, MS, NP; Kim Martin, RN; Kelly M. Makino, BS – Past Investigator; M. Saleem Ismail, MD – Past Investigator; Connie Brand, RN – Past Investigator; University of California Irvine: Steven G. Potkin, MD; Adrian Preda, MD; Dana Nguyen, PhD – Past Investigator. University of Texas Southwestern Medical School: Kyle Womack, MD; Dana Mathews, MD, PhD; Mary Quiceno, MD, NP – Past Investigator. University of California: Lisa Apostolova, MD; Daniel Marson, MD, PhD; Eric Foxhall, MD, PhD; Mary Tricco, MD, PhD; Daniel Marson, MD; Michelle Rainka, PhD; Hermann, MD – Past Investigator.
Mogo Clinic Jacksonville: Neill R. Graff-Radford, MBChB, FRCP (London); Francine Parfitt, MSH, CRCC; Kim Pi-Ko-Walker, BA, Indian University: Martin R. Farlow, MD; Ann Marie Hake, MD; Brandy R. Matthews, MD – Past Investigator; Jared R. Brosch, MD; Scott Herring, RN, CRCC; Yale University School of Medicine: Christopher H. van Dyck, MD; Richard E. Carson, PhD; Martha G. MacAvoy, PhD; Pradeep Vaidya, MD, McGill University Montreal Jewish General Hospital: Howard Chertkow, MD; Howard Bergman, MD; Chris Hosier, MD, Sunnybrook Health Sciences Ontario; Andrea Black, MD, FRCP; Bojana Stefanovic, PhD; Curtis Caldwell, PhD, UBC. Clinical for AD & Related Disorders: Ging-Yuek Robin Hsiung, MD, MHCDS, FRCP; Benita Mudge, BS; Vesna Sossi, PhD; Howard Feldman, MD, FRCP – Past Investigator; Michele Assaly, MA – Past Investigator. Cognitive Neurology St. Joseph’s, Ontario: Elizabeth Finger, MD; Stephen Pasternack, MD, PhD; Irina Rachisky, MD; Dick Trost, MD – Past Investigator; Andrew Kertesz, MD – Past Investigator. Cleveland Clinic Louis Ruvo Center for Brain Health: Charles Bernecki, MD, PhD – Past Investigator; Morgan G. McEwen, PhD; Northwestern University: Marek Marcel Mesulam, MD; Emily Rogalski, PhD; Kristine Lipowski, MA; Sandra Weintraub, PhD; Borna Bonakdarpour, MA; Diana Kerwin, MD – Past Investigator; Chuan-Kuo Wu, MD, PhD – Past Investigator; Nancy Johnson, PhD – Past Investigator. Premiere Research Inst (Palm Beach Neurology): Carl Sadowsky, MD; Teresa Villena, MD – Past Investigator. Georgetown University Medical Center: Raymond Scott Turner, MD; Kathleen Johnson, NP; Brigaid Reynolds, NP, Brigham and Women’s Hospital: Reisa A. Sperling, MD; Keith A. Johnson, MD – Past Investigator. University of Texas Southwestern Medical Center: Joseph Bermea, MD; Ryan M. Schenker, MD; Warren A. Mishkin, MD; Marc A. Mintun, MD – Past Investigator; Howard; Thomas O. Obisesan, MD, MPH; Saba Walter, MD; Bobi C. Halpern, MD – Past Investigator; Patrick Lawn, MD; Ronald Killiany, PhD; Andrew E. Budiman, MD – Past Investigator; Patricia Lynn Johnson, BA – Past Investigator. Howard University: Thomas O. Obisesan, MD, MPH; Saba Walter, MD; Joanne Allard, PhD – Past Investigator. University of Alabama at Birmingham: Alan Lemon, MD; Paula Ogrocki, PhD; Curtis Tatsuoka, PhD; Parianne Fatica, BA, CRCC. University of California, Davis – Sacramento: Evan Fletcher, PhD; Pauline Maillard, MD; John Olinchey, MD; Charles DeCarli, MD – Past Investigator; Owen Carmichael, MD – Past Investigator. Neurological Care of NY: Smita Kittur, MD – Past Investigator.
Parkwood Hospital: Michael Borrie, MB, CHB, T-Y Lee, MD – Dr Rob Bartha, PhD – Past Investigator. University of Wisconsin: Sterling Johnson, PhD; Sanjay Asthana, MD; Cynthia M. Carlsson, MD, PhD – Past Investigator; University of California, Irvine – BIC: Steven G. Potkin, MD; Adrian Preda, MD; Donald Nyswonger, PhD. Alzheimer’s Disease – Past Investigator; Peter Brown, PhD; Sadiq Nadir, MD, PhD; CRCC – Past Investigator; Adam Fleisher, MD – Past Investigator; Stephanie Reeder, BA – Past Investigator. Dent Neurologic Institute: Vernice Bates, MD; Horacio Capote, MD; Michelle Rainka, PhD; Hermann, MD – Past Investigator. Cleveland Clinic: Pierre Tarbot, MD; Anna Burke, MD; Torker Torker, MD; Sandra W. Milliken, NMD; Nadira Trncic, MD, PhD, CRCC – Past Investigator; Amanda Smith, MD; Andrew Kroon, MD; John Rogers, MD, PhD – Past Investigator. Alzheimer’s Disease Neuroimaging Initiative: Godfrey D. Pearson, MD; Karen Blank, MD; Karen Anderson, RN. Dartmouth Hitchcock Medical Center: Laura A. Flashman, MD; Marc Seltzer, MD; Mary L. Hynes, RN, MPH; Robert B. Santulli, MD – Past Investigator. Wake Forest University Health Sciences: Kaycee M. Sink, MD, MAS, Leisl Gordiner, Jeff D. Williamson, MD, MHS – Past Investigator. Prodege Gudjon, MD, PhD – Past Investigator; Franklin Watkins, MD – Past Investigator. Rhode Island Hospital: Brian R. Ott, MD; Jeffrey Tremont, PhD; Lori A. Daello, PharmD, ScM. Butler Hospital: Stephen Salloway, MD, MS; Paul Malloy, PhD; Stephen Correia, PhD. UC San Francisco: Howard J. Rosen, MD; Bruce L. Miller, MD; David Perry, MD – Past Investigator. South Carolina: Jacobo Mintzer, MD, MBA; Kenneth Spencer, MD; PhD; David Bachman, MD, St. Joseph’s Health Care: Elizabeth Finger, MD; Stephen Pasternak, MD; Irina Rachinsky, MD; John Rogers, MD; Andrew Kertesz, MD – Past Investigator; Dick Drost, MD – Past Investigator. Nathan Kline Institute: Nundho Pomara, MD; Raymond Hernandez, MD; Antero Sarrael, MD, University of Iowa College of Medicine: Susan K. Schultz, MD; Karen Ekstam Smith, RN; Kristina Koleva, MD; Ki Won Nam, MD; Hyungsub Shin, MD – Past Investigator. Cornell University: Norman Rekin, MD; PhD; Gloria Chiang, MD; Michael Lin, MD; Lisa Radvin, PhD. University of South Florida: USF Health Byrd Alzheimer’s Institute: Amanda Smith, MD; Balbinder Aslak Ajaj, MD; Kristin Fargher, MD – Past Investigator.
